Sentiment Analysis of Twitter Data

Abstract:

Social media platforms, particularly Twitter, have become important channels for expressing public opinions on events, products, and social issues. The large volume and unstructured nature of Twitter data make manual sentiment analysis difficult and inefficient. This project focuses on collecting Twitter data and preprocessing it by removing noise such as special characters, stop words, URLs, and irrelevant content to ensure data quality for effective analysis. The cleaned data is then transformed using text normalization, tokenization, and feature extraction techniques such as TF-IDF to convert textual information into numerical form.

Machine learning algorithms are applied to classify tweets into positive, negative, or neutral sentiment categories. The proposed system provides an automated and efficient sentiment analysis framework capable of handling large-scale Twitter data and identifying overall public opinion trends. This integrated approach improves sentiment classification accuracy and supports applications in market analysis, social research, and decision-making support systems.
